Calculation (Ca	alculation is either documented here or a	attached)			
See attached.					
Conclusions (S)	pecify whether or not the purpose of the	e calculation was acc	complished.)		
1. The maximum stress in the lamellae is 19 ksi, below the NSTX Design Criteria allowable to meet the fatigue requirements for 60,000 full-power cycles; 2.) The HeliCoil and SuperBolt stresses are below the maximum allowable to meet the fatigue requirement; 3.) The bolted joints were shown not to separate, and the minimum contact pressure is well above the design goal of 1500 psi. 4.) The dynamic load factor was calculated for the flex strap alone. A full transient electromagnetic disruption analysis using the worst-case combination of current and plasma disruption scenarios should be performed to fully qualify the joint and flex strap designs.

# NSTXU-CALC-132-06-01 TF Flex Joint and TF Bundle Stub

02-03-11

## **Study Goals**

#### Purpose:

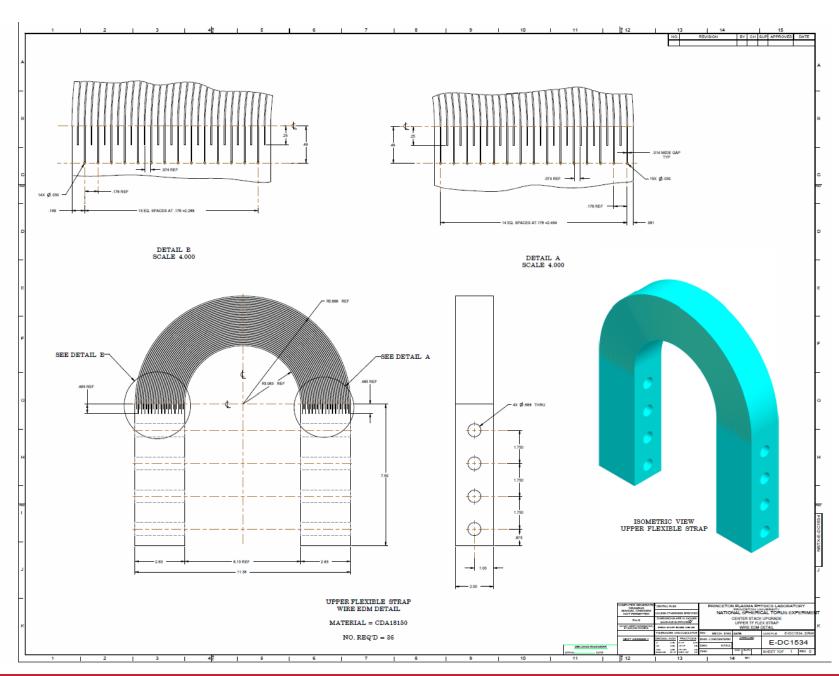

To determine if the upgrade TF flex joint and bundle stub design is adequate to meet the requirements of the NSTX Structural Design Criteria, specifically, the fatigue requirements of Section I-4.2 for 60,000 full power cycles without failure.

- Strap Lamellae
  - Stresses
  - Buckling
- Bolted Joints
  - Thread shear stress
  - Contact status and pressure

- Analysis
  - Magnetostatic
    - Magnetic Flux Density
    - Current Density
  - Transient Thermal
    - Temperature
  - Static Structural
    - Conductor Stress
    - Lamella Stress
    - · Thread and Bolt Stress
    - Contact Pressure
- Development Tests
- Conclusion

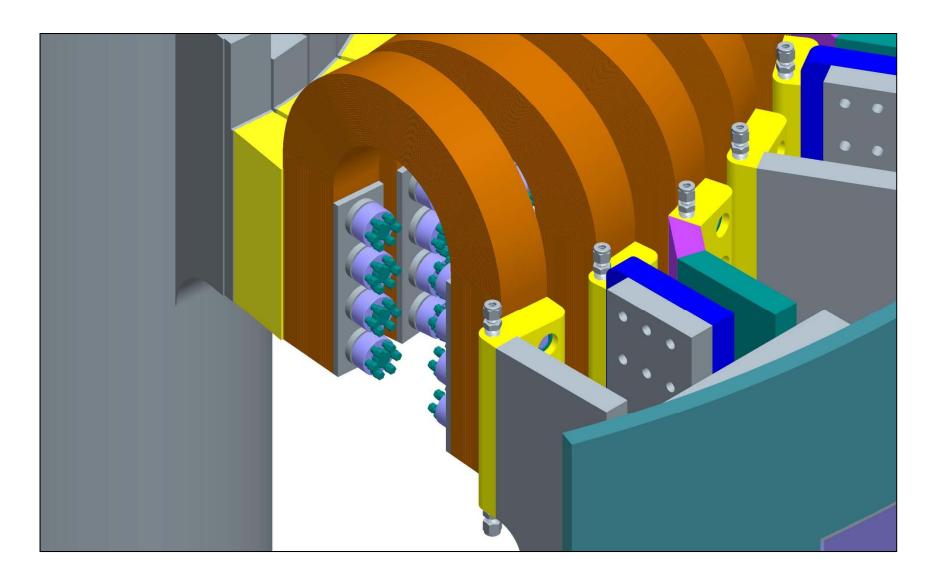

#### **NSTX CSU Flex Strap with Applied Boundary Conditions**

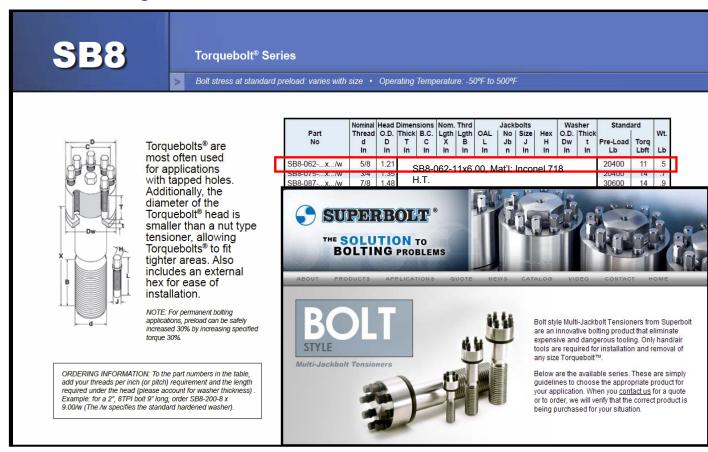

# Flex Joint Design using *Superbolt* Jack-Screw Tensioned Nuts

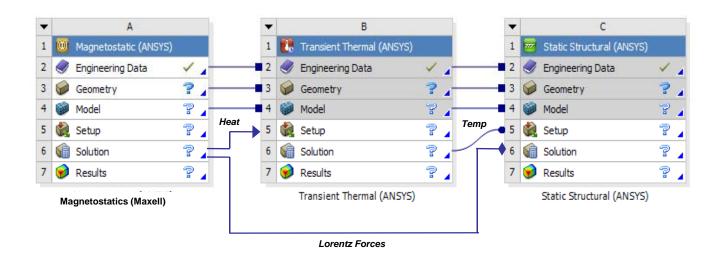

### Superbolt Jack-Screw Tensioned Nut

- Advantages of using Superbolts
  - Easy Installation and removal of individual flex assemblies
  - Low torque required: ~ 11 ft-lbf
  - Smaller inner-radius of flex strap required, allows use of more laminations, reducing the maximum lamination stress

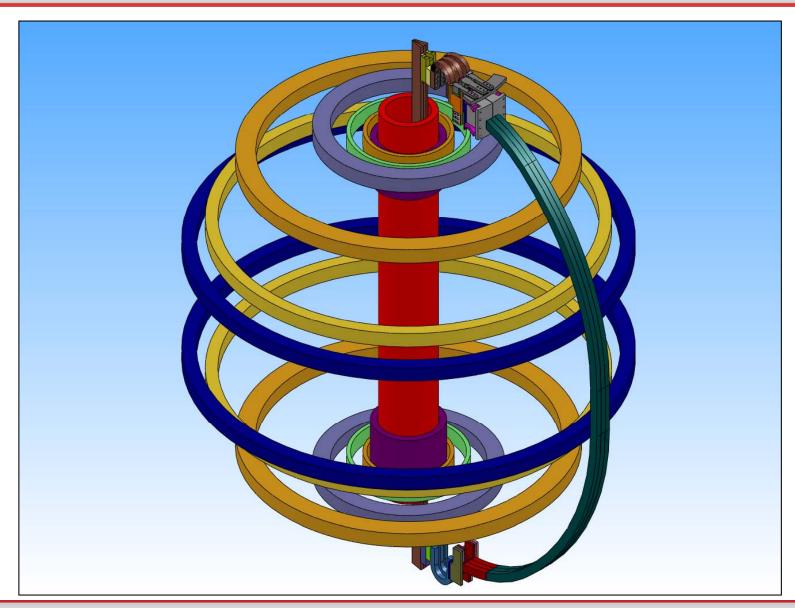

# Coupled *Maxwell* Magnetostatic and *ANSYS* Transient Thermal/ Static Structural Analysis Block Diagram

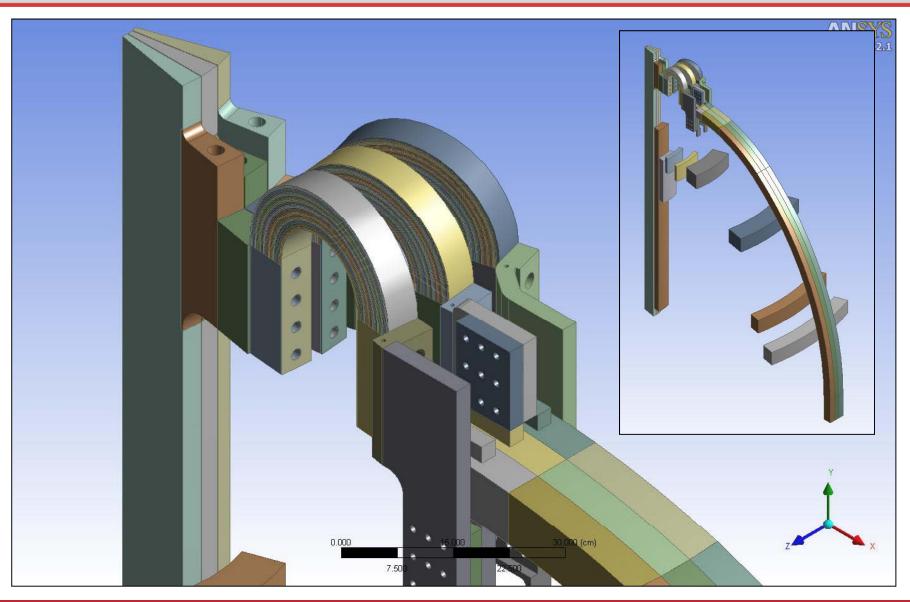

Note: This sequential, one-way coupled analysis is only valid if the bolted joints do not separate, and if the electrical and thermal contact resistances are a weak function of contact pressure, which is true in this case if the minimum local contact pressure is above 1500 psi.

#### Tests Performed at 3 Different Levels

- Material Level
  - C18150 H01 fatigue strength (R0)
- Stub Joint Level
  - HeliCoil insert pull-out strength in C18150 copper stub, static and fatigue
  - Inconel 718 custom Superbolt nut/ stud fatigue strength
- Flex Strap Assembly Level
  - Manufacturability
  - In-plane bending stiffness
  - · Cyclic, simulated maximum combined loads
  - Contact pressure distribution
    - Bolt pretension only
    - Bolt pretension + simulated maximum combined-load
  - Superbolt nut tensioned in umbrella segment mock-up

#### **Conclusions**

#### 1. Lamination Stress:

Excluding singularities, the maximum Tresca stress in the laminations is 18.9 ksi. To satisfy the requires of the NSTX Structural Design Criteria, the fatigue strength at 60 K cycles must be greater than twice this stress, or the fatigue strength at 1.2 E06 cycles (20x N) must be equal to or greater than this stress, whichever is the more severe requirement.

The fatigue S-N curve for C18150 copper-zirconium, with the maximum lamination Tresca stress
plotted at N = 60 K cycles, is shown above. The lamination stress is slightly below the 2x stress level
and meets all the requirement of the Design Criteria.

#### 2. Copper Flag Thread Stress:

The average shear stress in the copper threads is 34.8 ksi. To satisfy the Design Criteria, the shear stress must be less than 0.6 Sm = .4 Sy = 37.5 ksi.

The Modified Goodman diagram for C18150 copper-chromium-zirconium, with thread Tresca stress
plotted, is shown above. The thread stress meets all the requirements of the Design Criteria.

#### 3. Contact Status/ Pressure:

Results show that none of the joints separate, and that the minimum local contact pressure is approximately 2600 psi, which is 1100 psi above the minimum requirement.

Initial assumptions are correct, sequential one-way coupled model is valid.

#### 4. Lamination Buckling Load Multiplier Factor (LMF):

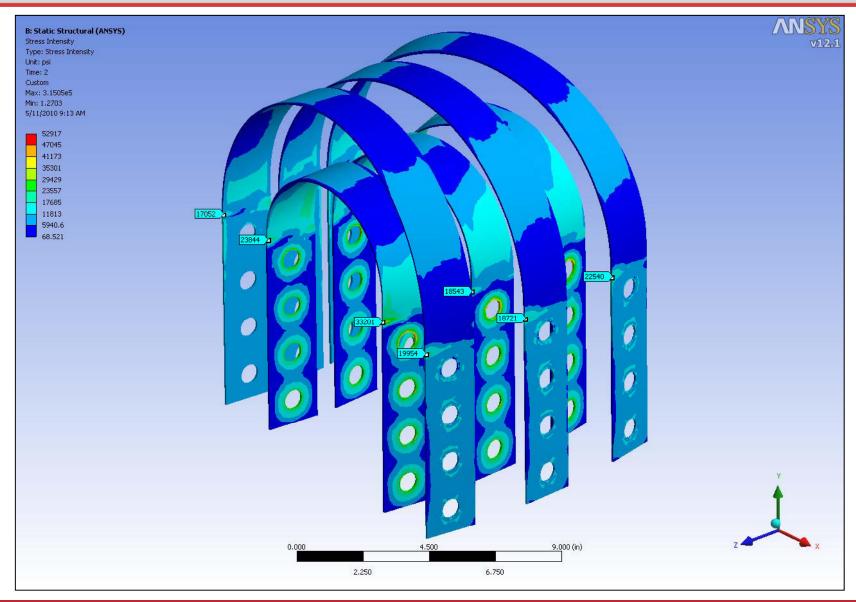

The 1<sup>st</sup> mode LMF is 58 (see Appendix), well above the Design Criteria linear buckling requirement of 5.

#### **HALF-SINE PULSE**

Consider the "half-sine" acceleration pulse (Fig. 31.20*A*) of amplitude  $\ddot{u}_m$  and duration  $\tau$ :

$$\ddot{u} = \ddot{u}_m \sin \frac{\pi t}{\tau} \qquad [0 \le t \le \tau]$$

$$\ddot{u} = 0 \qquad [t > \tau]$$
(31.34)

From Eq. (31.28), the effective duration is

$$\tau_r = \frac{2}{\pi} \ \tau \tag{31.35}$$

#### **VERSED SINE PULSE**

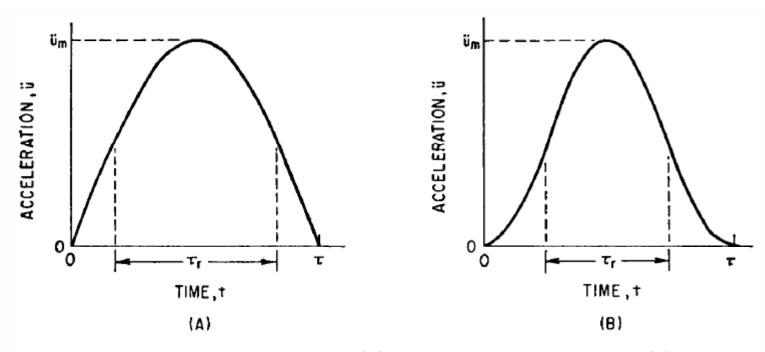

The versed sine pulse (Fig. 31.20B) is described by

$$\ddot{u} = \frac{\ddot{u}_m}{2} \left( 1 - \cos \frac{2\pi t}{\tau} \right) = \ddot{u}_m \sin^2 \frac{\pi t}{\tau} \qquad [0 \le t \le \tau]$$

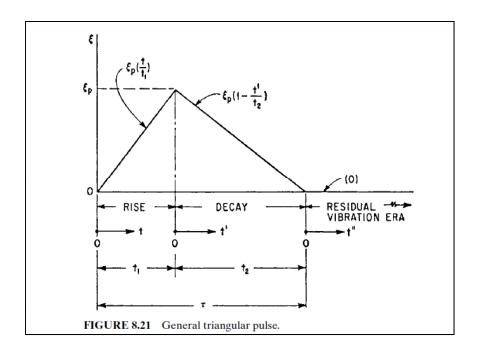

$$\ddot{u} = 0 \qquad [t > \tau]$$
(31.36)

The effective duration  $\tau_r$  given by Eq. (31.28) is

$$\tau_r = (\frac{1}{2})\tau \tag{31.37}$$
